

Cosmological Radiative Transfer Comparison Project

Ilian Iliev
ITP, University of Zurich

Project website: <http://www.cita.utoronto.ca/~iliev/rtwiki/doku.php>

Motivation and Basic Strategy

- The full RT problem is very expensive, multi-dimensional problem, so approximations are inevitably required.
- Our aim is to validate our codes and evaluate their reliability and limitations, on the way creating a development testbed for future codes.
- Very few, simplified problems have exact analytical solutions to check RT codes against.
- Next best approach – compare results from independent codes on common problems.
- Problems: simple and clean, of increasing difficulty, involving astrophysically-interesting situations.
- Everybody is welcomed to join. Regular workshops. Results published in series of papers and at a

Organization

- Open project: everybody free to join.
- Open-ended project – continually updated and new tests/new physics added.
- Any problem would be considered, but for inclusion min 3 codes should do it.
- Regular workshops (2 to date, another soon).
- Papers on results published after each stage of the project is completed.
- Project and analysis coordinated by a single person, with help from

Cosmological Radiative Transfer Comparison Project

Radiative transfer simulations are now at the forefront of numerical astrophysics. They are becoming crucial for an increasing number of astrophysical and cosmological problems; at the same time their computational cost has come within reach of currently available computational power. Further progress is retarded by the considerable number of different algorithms developed, which makes the selection of the most suitable technique for a given problem a non-trivial task. The aim of this comparison project is to assess the validity ranges, accuracy and performances of these schemes. Currently 13 independent RT codes are participating in this project. They are being tested on 8 test problems: (0) basic physics; (1) isothermal HII region expansion; (2) HII region expansion with evolving temperature; (3) I-front trapping and shadowing by a dense clump; (4) multiple sources in a cosmological density field; (5) classical HII region gasdynamic expansion; (6) HII region gasdynamic expansion in $1/r^2$ density profile, and (7) photoevaporation of a dense clump. The present results and tests represent the most complete benchmark available for the development of new codes and improvement of existing ones. To further this aim all test inputs and outputs are made publicly available in digital form at this website.

Test descriptions, data submission, papers and workshops

Description of the tests and of the required data format for submission.

Submit data here.

The first paper, The Static Density Field Tests: [ArXiv](#), [ADS](#)

To date we have organized two workshops related to this comparison project:

First workshop

Second workshop

Results: Static Density Field Tests

Here we would publish results which were not included in Paper I of our Comparison Project, as well as any errata and corrections to the published results.

Corrections

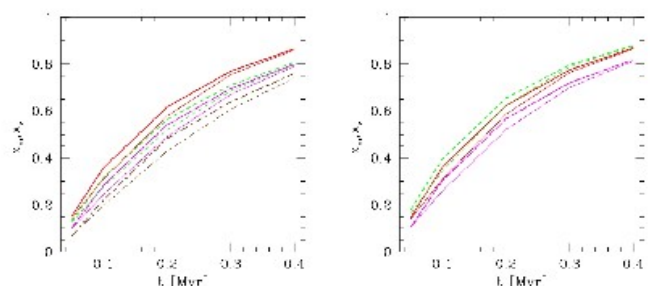

Figure 35 in Paper I had incorrect time axis, the corrected version of the figure is shown here. We thank Dominique Aubert for pointing this out.

Data

The data files provided are in standard IFRIT [binary](#) (little-endian) format. The first line lists the grid dimensions (here 128 128 128 for all data) and then the 3D arrays for each variable in the order requested.

Table of Contents

Done

Data Formats

- Maximally simple and machine independent.
- Submission: ASCII data, defined loops and variables order, evolution times at which data is required (typically 5 timeslices, to limit total data amount).
- (Relatively) Low resolution requested (128^3 grid) in interests of inclusivity.
- For standartization data required on a regular grid – not optimal for all codes (e.g. AMR, Lagrangean, unstructured grids).

Issues and problems

- People need regular pushing along, or nothing will happen.
- A number of issues with the data submissions (inevitable when a number of busy people involved?) – significant amount of time and efforts to fix:
 - incorrect data format of submissions (e.g. multiple files instead of one).
 - incorrect variable (e.g. HII instead of HI fraction).
 - different units (e.g. cm vs. kpc, sec vs. Myr).
 - more subtle – in some cases slightly incorrect/different problem ran (e.g. different ionizing spectrum used)

Cosmological Radiative Transfer: specifics

- Main problem: Reionization of the Universe by the first sources.
- Large scales (from kpc to hundreds of Mpc), up to hundreds of thousands of sources.
- Low densities \rightarrow fast I-fronts (R-type), converting to D-type in denser regions (halos).
- 3D, inhomogeneous density fields.
- Very high optical depths.
- H+He are most important, but metal cooling also matters at later times

Tests: 0-7

- Test 0 : Basic physics, rates used + single zone evolution in ionizing up and then recombining

Pure radiative transfer tests:

- Test 1: Pure hydrogen isothermal HII region expansion
- Test 2: HII region expansion: the temperature state (H+He or pure H)
- Test 3: I-front trapping in a dense clump and formation of a shadow (w/point source and plane-parallel flux)
- Test 4: Multiple sources in a (fixed)

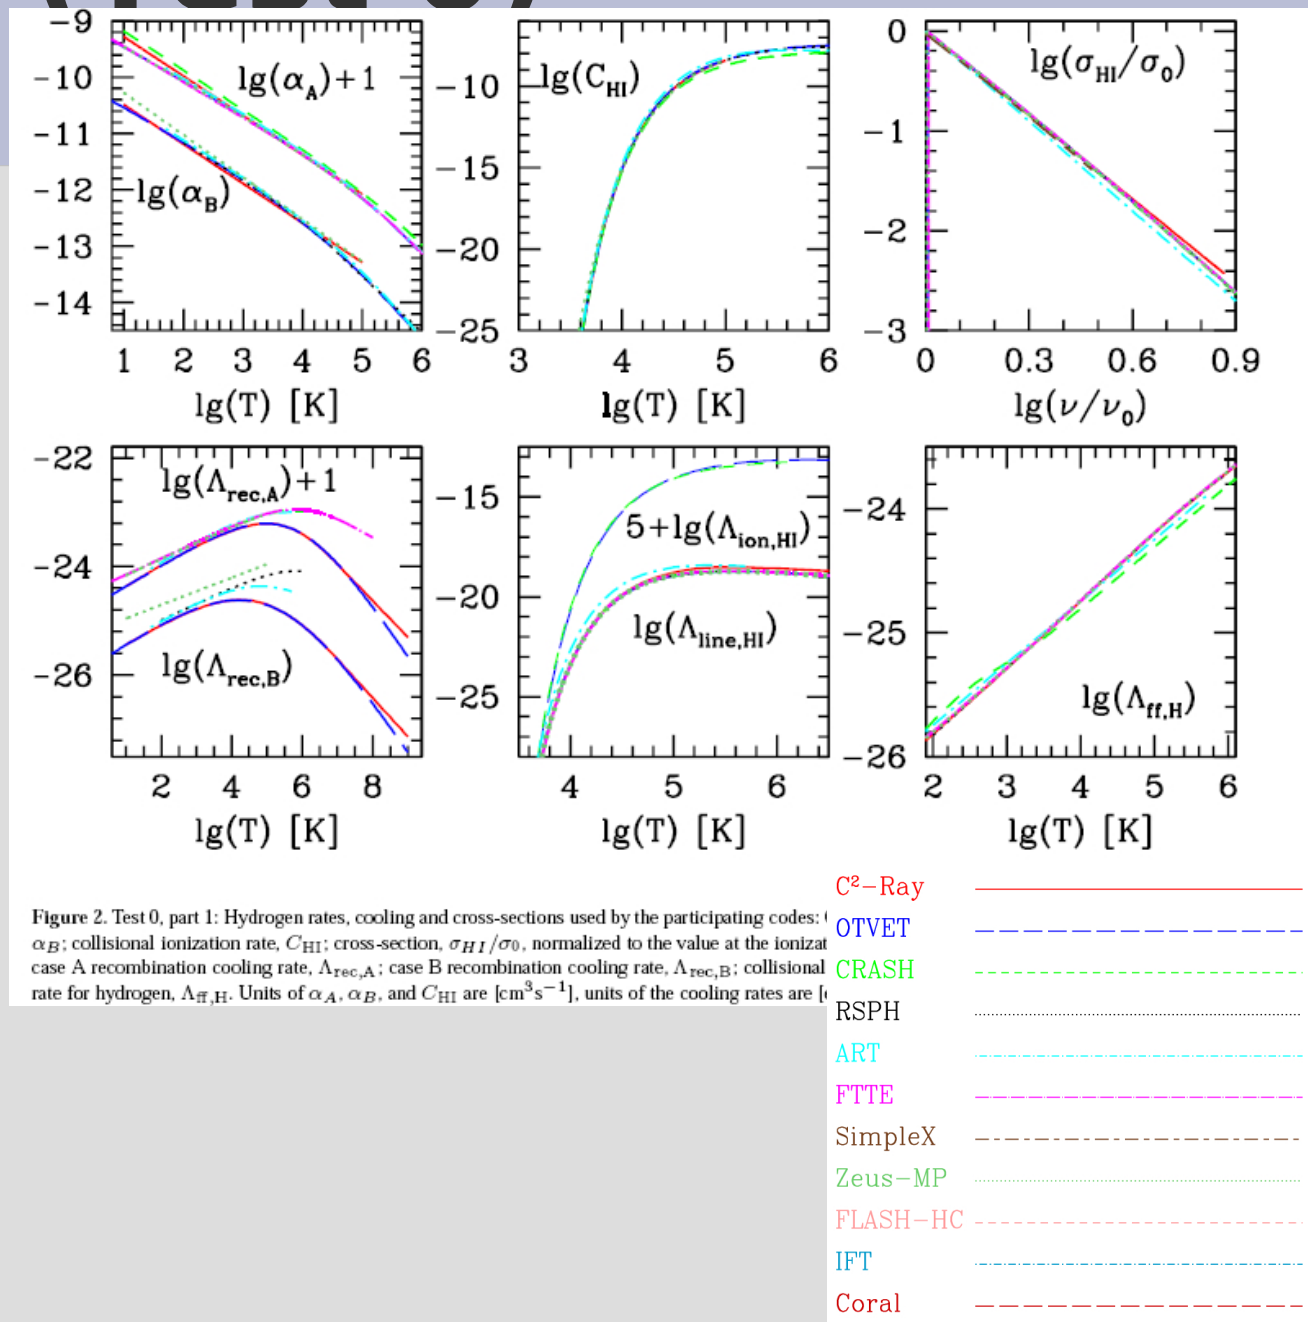

Tests: 0-7 (cont.)

Radiative hydrodynamics tests:

- Test 5: Classical HII region expansion and R-type to D-type transition
- Test 6: HII region expansion in $1/r^2$ profile: (re-)acceleration down a steep density profile and inside-out dwarf galaxy photoevaporation
- Test 7: Photoevaporation of a dense clump (w/point source and plane-parallel flux)

Chemistry and Cooling Rates (Test 0)

Chemistry and cooling rates vary significantly between sources in literature – this can introduce noticeable variations in the results.

Chemistry and Cooling Rates: effects

same RT method, different rates

Examples. Test 2. Initial expansion

Figure 11. Test 2 (H II region expansion in a uniform gas with varying temperature): Images of the H I fraction, cut through the simulation volume at coordinate $z = 0$ at time $t = 10$ Myr for (left to right and top to bottom) C²-Ray, OTVET, CRASH, RSPH, ART, FTTE, and IFT.

Test 2: I during Initial expansion

Figure 12. Test 2 (H II region expansion in a uniform gas with varying temperature): Images of the temperature, cut through the simulation volume at coordinate $z = 0$ at time $t = 10$ Myr for (left to right and top to bottom) C^2 -Ray, OTVET, CRASH, RSPH, ART, FTTE, and IFT.

Test 2: Stromgren sphere

Figure 13. Test 2 (H II region expansion in a uniform gas with varying temperature): Images of the H I fraction, cut through the simulation volume at coordinate $z = 0$ at time $t = 100$ Myr for (left to right and top to bottom) C²-Ray, OTVET, CRASH, RSPH, ART, FTTE, and IFT.

Test 2: Stromgren sphere T

Figure 14. Test 2 (H II region expansion in a uniform gas with varying temperature): Images of the temperature, cut through the simulation volume at coordinate $z = 0$ at time $t = 100$ Mvr for (left to right and top to bottom) C²-Ray, OTVET, CRASH, RSPH, ART, FTTE, and IFT.

Test 2: ionization structure

1 gas with varying temperature): Spherically-averaged ionized fraction x and neutral fraction $1-x$

Test 2: temperature structure

Figure 17. Test 2 (H II region expansion in a uniform gas with varying temperature): Spherically-averaged temperature profiles at times $t = 10$ Myr, 100 Myr and 500 Myr (from left to right).

Test 2: x and T histograms

Figure 18. Test 2 (H II region expansion in a uniform gas with varying temperature): Fraction of cells with a given ionized fraction, x , at times (left) $t = 10$ Myr, (middle) 100 Myr and (right) 500 Myr.

Figure 19. Test 2 (H II region expansion in a uniform gas with varying temperature): Fraction of cells with a given temperature T at times (left) $t = 10$ Myr, (middle) 100 Myr and (right) 500 Myr.

Summary

- Chemical reaction and cooling rates are still somewhat uncertain – can give up to 10-30% difference in outcome. Equilibrium chemistry is generally not a good approximation.
- All methods track I-fronts fairly well, yield reliable results. Some methods could introduce unphysical anisotropies, however.
- The largest discrepancies are due to imprecise treatments of the energy equation (temperature) and of the multi-frequency photons (spectral hardening) – the best approach is very problem-dependent.
- Radiative-hydrodynamics direct coupling – inherently more complex. Still results are relatively consistent between different methods, but there are also some significant and nontrivial variations, which require further careful study.
- It is important to evaluate the limitations of each code, some methods could underperform or even fail in certain situations
