

Did Star-Forming Galaxies Reionize the Universe?

Richard Ellis, Caltech

First Stars & Galaxies

Austin, TX March 10th 2010

Theorists' View of Cosmic Reionization

LIGHTING UP THE COSMOS

In the beginning of the Dark Ages, electrically neutral hydrogen gas filled the universe. As stars formed, they ionized the regions immediately around them, creating bubbles here and there. Eventually these bubbles merged together, and intergalactic gas became entirely ionized.

Avi Loeb, Scientific
American 2006

Simulated images of 21-centimeter radiation show how hydrogen gas turns into a galaxy cluster. The amount of radiation (*white is highest; orange and red are intermediate; black is least*) reflects both the density of the gas and its degree of ionization: dense, electrically neutral gas appears white; dense, ionized gas appears black. The images have been rescaled to remove the effect of cosmic expansion and thus highlight the cluster-forming processes. Because of expansion, the 21-centimeter radiation is actually observed at a longer wavelength; the earlier the image, the longer the wavelength.

Time:
Width of frame:
Observed wavelength:

210 million years
2.4 million light-years
4.1 meters

All the gas is neutral. The white areas are the densest and will give rise to the first stars and quasars.

290 million years
3.0 million light-years
3.3 meters

Faint red patches show that the stars and quasars have begun to ionize the gas around them.

370 million years
3.6 million light-years
2.8 meters

These bubbles of ionized gas grow.

460 million years
4.1 million light-years
2.4 meters

New stars and quasars form and create their own bubbles.

540 million years
4.6 million light-years
2.1 meters

The bubbles are beginning to interconnect.

620 million years
5.0 million light-years
2.0 meters

The bubbles have merged and nearly taken over all of space.

710 million years
5.5 million light-years
1.8 meters

The only remaining neutral hydrogen is concentrated in galaxies.

Wonderful..but did it really happen like this..?

Why the Early Universe? Grand Questions

- **What** - reionized the universe and were star-forming galaxies the primary agents?
- **When** - did reionization occur? Was it a sudden, protracted or even two-stage process?
- **How** - did it proceed? What processes defined the emerging mass function of galaxies
- **Then What?** - Implications for the subsequent development of galaxies and the IGM

Mostly a review, but with some collaborative material from:

Brant Robertson (CIT), Dan Stark (IoA), Masami Ouchi (OCIW), Eiichi Egami (Arizona), Andy Bunker (Oxford), Jim Dunlop & Ross McLure (Edinburgh), Jean-Paul Kneib (Marseilles), Johan Richard (Durham),

When? WMAP Polarization

$\tau = 0.17 \pm 0.08$ (WMAP1, 2003)
 $\tau = 0.09 \pm 0.03$ (WMAP3, 2007)
 $\tau = 0.087 \pm 0.017$ (WMAP5, 2009)
 $\tau = 0.088 \pm 0.015$ (WMAP7, 2010)

Dunkley et al 2009
 Jarosik et al 2010

Data rejects instantaneous reionization at $z \sim 6-7$

Process is likely extended over $6 < z < 20$

CMB studies do not pinpoint the responsible cosmic sources

Ionized Carbon Absorbers in High z QSOs

IR spectra of 10 QSOs with “absorption distance” $X(z>5)\sim 25$ to $\log n_{\text{CIV}}\sim 14.2$

Complementary deeper search with $X\sim 11$ to $\log n_{\text{CIV}}\sim 13.4$ (Becker et al 2009)

Ryan-Weber et al (2009)

Rapid drop in Ω_{CIV} from $z=4.5$ to $z=6$

$\times 3.5$ drop in Ω_{CIV} (4σ) over 300 Myr ($4.7 < z < 5.8$)

- Suggests rapid enrichment since $z \sim 9$ (c.f. Oppenheimer et al [vzw model](#))
- Caveats: ionization changes, blending (c.f Becker et al), cosmic variance
- If absorbers representative: $Z_{\text{IGM}}(z \sim 6) \sim 10^{-4} Z_{\odot}$ (depends on ionizⁿ)
- Puzzle: implies too few escaping photons ($6 < z < 9$) to keep IGM ionized

High Redshift Star Forming Galaxies

Lyman break galaxies (LBGs):

Rest-frame UV continuum discontinuity

Lyman alpha emitters (LAEs):

Located via narrow band imaging

Star formation density of LBGs

Monotonically declining population to $z \sim 6$ and beyond

Drop of $\times 8$ in UV luminosity density $2 < z < 6$

Appealing indicator: but 'observed SF' may be misleading guide

Reddy & Steidel (2009); Bouwens et al (2009)

Spitzer Revolution: Stellar Masses & Ages

A modest 85cm cooled telescope can see the most distant known objects and provide crucial data on their assembled stellar masses and ages

SMB03-1: $z_{\text{spec}}=5.83$ IRAC(3.6 μm)=24.2 (AB)
 stellar mass = $3.4 \times 10^{10} M_{\odot}$ age > 100 Myr

Eyles et al (2005): to produce this mass since $z \sim 10$ required $5\text{-}30 M_{\odot} \text{ yr}^{-1}$
 comparable to the ongoing SFR ($6\text{-}20 M_{\odot} \text{ yr}^{-1}$)
 so should see earlier examples if unobscured

Balmer Break as Age Indicator

Age is degenerate with star formation history but can infer **time-averaged star formation rate** and compare this with actual **on-going star formation rate**

Stellar Mass Functions $4 < z < 6$ (Stark et al 2009)

- 2443 B-drops, 506 V-drops, 137 i-drops in ACS GOODS N/S
- 35% sufficiently isolated with Spitzer/IRAC for robust photometry
- Deep K imaging from ISAAC (Cesarsky), MOIRCS (Bundy)
- Low z contaminants identified (morphology, MIPS)
- Masses and ages using CB07, testing effect of TP-AGB stars
- Individual measures to $M \sim 10^{9.5} M_{\odot}$; stacked properties for fainter sources

Examples across the full range of data

High mass/bright

mass = $2.3 \cdot 10^{10} M_\odot$

age = 290 Myr

Low mass/faint

mass = $4.8 \cdot 10^9 M_\odot$

age = 320 Myr

Stacked data

mass = $1.7 \cdot 10^8 M_\odot$

age ~ 50 Myr

Stellar Mass Density

$$M_*(z) = \int_{z=5}^{z=10} \rho_*(z) dV(z)$$

Stellar mass density at $z \sim 5-6$ implies past SF in low luminosity galaxies may be sufficient for reionization, especially if escape fraction is high

Stark et al 2007,2009; Labbé et al 2009ab

Ages of $z\sim 4-7$ galaxies from Spitzer data

- Mass $\div$ SFR gives 'effective age'; low mass/UV faint galaxies younger
- Ages are short (< 300 Myr) and don't lengthen as Universe ages!
- Successive generations arriving, consistent with faster cycles of SF at high z

Stark et al Ap J 697, 1493 (2009)

Wide Field Imaging of LAEs from Subaru

Panoramic imaging with Subaru using narrow-band filters has been used to locate high redshift Ly α emitters (LAEs)

As much as 7% of the total output of a young galaxy can be in this single emission line (so v. efficient for survey work)

LBGs vs LAEs: Very Different Evolution

LBGs: Marked decline in UV luminosity density with redshift over $3 < z < 6$

LAE: no evolution to $z \sim 5.7$

Increasing dominance of $\text{Ly}\alpha$ emission at high z

Reduced dust; HI covering fraction, faster duty-cycle of SF?

Probes of Reionization: - Lyman α emitters

- Ly α damping wing is absorbed by HI and thus valuable tracer of its presence.
- In weaker systems, it may be a **sensitive probe of reionisation**
- Complicated by clumping of dust? (Dayal et al 1002.0839)
- Require detailed modeling of radiative transfer? (Zheng et al 0910.2712)

Santos MN 349, 1137 (2004)

McQuinn et al MN 381, 75 (2007)

Radiative Transfer Modeling of Ly α Emission

Spatial diffusion of Ly α photons leads to numerous complications: surface brightness biases, viewing angle & velocity structure dependencies

Zheng et al (0910.2712)

A Rapid Drop in Ly α Emitters from $5.7 < z < 6.6$?

- 1 deg² SXDS field with 608 photometric and 121 spectroscopic Ly α emitters
- Contrast with LBGs: no evolution $3 < z < 5.7$!
- Tantalizing fading (0.^m3) seen in the LF of Ly α emitters over a small redshift interval $5.7 < z < 6.6$ (150 Myr)
- Does this mark the end of reionization corresponding to an increase in x_{HI} (e.g. $x_{\text{HI}} \sim 0.6$ at $z \sim 7$)?

Ouchi et al (2010)

Keck Spectroscopic Survey of $4 < z < 7$ LBGs

- B, V, I, z drops in GOODS/UDF from Stark et al (09) ACS/IRAC catalog
- 8-16 hr exposures with DEIMOS to $m_{AB}=26.5$ (emission lines to $m_{AB}\sim 27.5$)
- Keck/DEIMOS: 361 B + 141 V + 45 I + 17 z-drops = 564 targets
- VLT/FORS2 retro-selected + same criteria: 195 targets (Vanzella et al)

Probing sub- L^* B,V drops

Stark et al (2010) MN submitted

Sample Keck Spectra (R~2500)

m=24.15, z=4.01

m=26.4, z=5.19

m=25.9, z=4.35

m=27.4, z=3.87

m=26.4, z=3.74

m=26.3, z=5.45

$\text{Ly}\alpha$ fraction vs UV luminosity and extinction

Strong correlation between extinction- inferred from UV slope β
(flux $\sim \lambda^\beta$) and presence/absence of $\text{Ly}\alpha$

Strongly suggests low luminosity galaxies are relatively dust-free
So their $\text{Ly}\alpha$ fraction might be valuable probe of reionization

Stark et al (2010) MN submitted

Boosting the signal with gravitational lenses

Critical line discoveries in Abell 2218

RSE et al 2001, Kneib et al 2004

Deciphering past history of $z \sim 6.8$ lensed LBG

Hubble

Spitzer

Hubble

Spitzer

Multiply-imaged $z=6.8$ galaxy in cluster Abell 2218; magnification $\times 25$

Star formation rate = $2.6 \text{ M}_{\odot} \text{ yr}^{-1}$ Stellar mass $\sim 5\text{--}10 \times 10^8 \text{ M}_{\odot}$

Balmer break gives age = 100 – 450 million yrs, so formed at $9 < z_F < 12$

This is already a well-established system 800 Myrs after Big Bang

Egami et al (2005)

Lensed Dropouts with HST/Spitzer

- 6 well-constrained clusters with deep IRAC imaging
- 4 orbits J/F110W; 5 orbits H/F160W, ACS/F850LP imaging
- K-band from Keck/NIRC + Subaru/MOIRCS
- 8 candidates $z \sim 7.5$ of which expect 2 (statistically) to be spurious/foreground
- Statistically conclude there are 6 credible candidates

Richard et al (2008) Ap J 685, 705

Spectroscopic Followup (Keck NIRSPEC)

Angular distribution c.f. critical lines further supports a low foreground contamination but 4 hour exposures of 7/8 candidates with NIRSPEC failed to detect Ly α emission (as in A2218 $z \sim 6.8$ source)

Ly α Emission Statistics versus Redshift

- Keck survey avoids confusion with dust as can also measure β
- Do not confirm $5.7 < z < 6.6$ drop seen in the Subaru LAE LF
- **But rising fraction with z puzzle: why no $z > 7$ candidates with Ly α ?!!**

Stark et al (2010) MN submitted

Summary ($z < 7$)

- WMAP polarization data rules out instantaneous reionization at late times ($z \sim 6-7$); expect extended phase with sources distributed over $7 < z < 20$
- Rapid rise in CIV abundance over $4.5 < z < 6$ supports prompt enrichment since $z \sim 9$
- Assembled stellar mass at $z \sim 5-6$ indicative of much earlier SF
- Drop in Ly α LF over $5.7 < z < 6.6$ may indicate modest increase in neutral fraction to $z \sim 7$ or perhaps cosmic variance/other obscuration – implications unclear
- Rising Ly α fraction over $4 < z < 6.5$ in equivalent LBG population makes dearth of emission in many $z > 7$ candidates puzzling

Upshot: Expect abundant population of SF sources $z > 7$
Possibly sub-luminous/obscured (and not emitting Ly α)
making spectroscopic verification very tough

Hubble Ultradeep Field

Hubble WFC3 High z Stampede

WFC3/IR: 850 - 1170nm

$z > 7$ candidates from WFC3 UDF campaign

688: $z_{\text{best}} = 6.70 (6.50 - 6.90)$

3 IR filters c.f. 2 leads to more secure photometric redshifts and reliable UV continuum slopes

McLure et al (2009)

But beware..uncertain redshifts still an issue..

Z Y J H

1678: $z_{\text{est}} = 7.05$ (6.60 – 7.40)

1107: $z_{\text{est}} = 7.60$ (7.30 – 7.90)

Requirements for Reionization by Galaxies

Several workers have suggested the abundance and properties of SF galaxies over $7 < z < 10$ may drive cosmic reionization

Variously accounted for in terms of C_{HII} , n_{y} , f_{esc} , Δt , ρ_{SFR} , IMF..

In fact, there are only 3 basic requirements:

- A sustained output from star-forming galaxies over $7 < z < 10$ (continuity in trends over $\Delta t \sim 300$ Myr)
- A steep faint end slope ensuring high fraction of UV photons arises from abundant sub-luminous sources ($\alpha < -1.8$), i.e. ρ_{SFR}
- A high escape fraction of ionizing photons ($f_{\text{esc}} > 0.2$) via improved understanding of UV slope β

Prospects for resolving ambiguities in next 2-3 years is promising via

- current UDF campaign (Illingworth 105W, 125W, 160W)
- shallower GOODS MCT campaign (Faber/Ferguson)
- proposed deeper targeted UDF campaign (105W, 140W, 160W)

WFC3 Progress – I: Continued SF decline $3 < z < 8$

Bouwens et al astro-ph/0909.1803

IRAC Detections of Luminous Galaxies @ $z \sim 7$: Evidence of Star Formation at Earlier Epochs

11 objects in GOODS/UDF
 $M < 10^{10} M_\odot$ ages < 400 Myr

Gonzalez et al 2009

$z \sim 10$? Bouwens et al vs Yan et al

Bouwens et al 0912.4263

Yan et al 0910.0027

Bunker et al: no convincing J-drop candidates to $H \sim 28.5$

Yan et al: 20 J-drops to $H \sim 29$

Bouwens et al: 3 J-drops to $H \sim 29$

One band detections and no candidate in common.....

Improved Identification of $z \sim 9$ Sources

Ultra-deep F105W and additional F140W

WFC3 Progress – II: $z \sim 7$ Luminosity Function

- ~25 z -band dropouts to $Y_{\text{AB}} \sim 28.5$ corresponding to $6.5 < z < 7.5$
- Steep faint end slope: low star formers $\sim 1 M_{\odot} \text{ yr}^{-1}$ dominant as predicted from lensed surveys

Oesch et al, Bunker et al 2009, 2010

Improved Measures of Faint End of LF

Increased depth in F105W and combined F140W+F160W

Brighter MCT
proposal with
larger area will
improve LF at
 $z \sim 7$ but still
leave major
uncertainties

Additional
depth would
reduce these
uncertainties

WFC3 Progress – III: Strong UV Continua?

WFC3 data provides Y+J+H data and first reasonable estimate of the slope β of the stellar continuum where $f(\lambda) \propto \lambda^\beta$: remarkably steep values $\beta \rightarrow -3$!

Strong trend of increasingly steep UV continua for high z , low L sources

Bouwens et al 2009

Bunker et al 2009

Can One Link β to the Escape Fraction f_{esc} ?

3 questionable assumptions:

- Including nebular continuum corresponds to $f_{\text{esc}} \sim 0$; pure stellar continuum to $f_{\text{esc}} \sim 1$.

- Intermediate mixtures can be linearly interpolated

- In burst models, can simply 'average' over a duty cycle to get representative relationship

Robertson et al (2010)

Escape fractions in $z \sim 3$ LBG spectra

$$f_{esc,rel} = \frac{(L_{1500}/L_{900})_{int}}{(f_{1500}/f_{900})_{corr}}$$

$$f_{esc} = 10^{-0.4 \times 10.33 E(B-V)} f_{esc,rel}$$

11/110 LBG spectra show positive Ly continuum flux
For that small subset, intriguingly, f_{esc} correlates as L^{-1}

Bogosavljevic (2009)

Upshot: Did galaxies reionize the Universe?

Emission rate of ionizing photons Mpc^{-3} vs C_{HII} and f_{esc} compared to abundance of star-forming galaxies

After Bolton & Haehnelt (2007), Ouchi et al (2009), Robertson et al (2010)

Future Prospects

- Continued improvement in $4 < z < 7$ spectroscopic surveys:
much to learn about demographics of LBGs/LAEs including spatial mapping of populations
- Multi-slit IR spectrographs for following existing and other $z > 7$ candidates
 - MOSFIRE on Keck (2011A)
 - KMOS on VLT (2011B)
- HST + WFC3:
 - Multi-cycle Treasury program (improved $z \sim 7$ LF)
 - Deeper UDF and other campaigns to probe fainter sources
- Adaptive optics imaging: all $z > 6$ sources will benefit, lensed sources are only 30 milliarcsec across!
- JWST (2014) and..not too far off..(2018)..TMT/E-ELT

LOTS TO LOOK FORWARD TO!

MOSFIRE (Keck I) - 2010B

Cryogenic Multi-slit IR spectrograph
6.1 x 3.1 arcmin spectroscopic field
 $\lambda\lambda 0.97 - 2.45$ microns
 $R \sim 3300$ for 0.7 arcsec slit
45 slits via configurable slit unit
(< 5 mins)

AO impacts JWST-TMT Synergy

- TMT with AO will have better resolution than JWST (*not a dream: Keck AO has better resolution than HST*)
- together with large aperture significantly changes space-ground synergy

First sources & cosmic reionization:

- TMT is key to locating more abundant, fainter, smaller sources (AO gives $\times 10$ -100 gain over JWST depending on angular size).
- JWST probes to higher z in mid-IR

Lensed galaxies at $z \sim 6$
Unlensed sizes $\sim 150\text{pc}$ or $< 30\text{mas}$!

Conclusions & Future Prospects

- Exciting time in the study of $z > 7$ galaxies with HST, Spitzer and large telescopes still in the vanguard
- Dramatic progress with deep IRAC observations:
from a couple of $z \sim 6$ detections in 2005 to comprehensive measures of the stellar mass density over $4 < z < 7$
- WFC3/IR has led to a flurry of new results:
galaxies may maintain reionization over $7 < z < 10$ if:
 - continuity of SF trends over 300 Myr
 - dominant fraction of sub-luminous galaxies
 - increased escape fraction
- Many uncertainties but good prospects for better data from HST
- Key role of future ELTs exploiting adaptive optics with JWST
