(Spring 2005)

The History and Philosophy of Astronomy

**(Lecture 26: Modern Developments I:
The Dark Side)**

Instructor: Volker Bromm
TA: Amanda Bauer

The University of Texas at Austin

The Dark Side of the Universe

- Big Q: What is the universe made of?

- consensus view of early 21st century (WMAP):
 - 4% normal matter ('baryons') (stars, gas, people...)
 - 23% dark matter
 - 73% dark energy

“Deep into the darkness peering, long I stand there wondering, fearing.” (E.A. Poe, *The Raven*)

- We don't know what > 90% of universe is made of !!!

Fritz Zwicky: Astronomy's Mad Genius

- Swiss national
1898 (Varna) – 1974 (Pasadena)
- Professor at Caltech (1925+)
- creative genius:
 - concept of supernova
 - neutron stars
 - dark matter ('missing mass')
- intense eccentricity
("spherical bastards")

1933: Zwicky and the 'Missing Mass'

- Coma cluster of galaxies
 - ~1,000 individual galaxies
 - 300 million lightyears away
- Zwicky measures average (radial) velocities (from Doppler shift)
 - Result: ~1,000 km/sec
- comparison with sum of visible (stellar) mass
- BIG surprise: There must be 10 times more matter !

1933: Zwicky and the 'Missing Mass'

- measure: V and R
- calculate required mass to hold cluster together:

$$M = \frac{V^2 R}{G}$$

(Newton's constant)

- Result for Coma:
 - need 10 times more mass than is visible!
- For more than 30 years, no one else took this seriously!

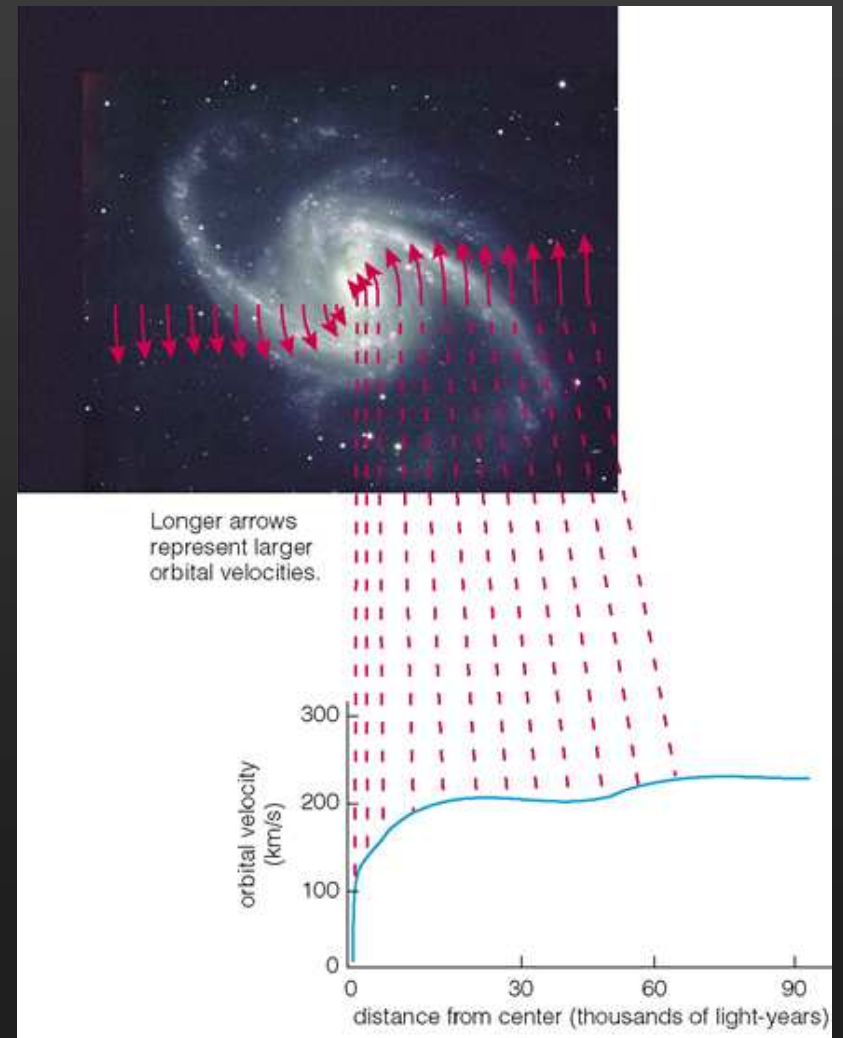

Vera Rubin: The Dark Side of Galaxies

- Born 1928 (Philadelphia)
- 1965: Carnegie Institution (DTM, Washington D.C.)
- firmly established existence of dark matter in individual galaxies (with Kent Ford)
 - flat rotation curves
- activist for women's rights in the sciences

Vera Rubin: The Dark Side of Galaxies (1970s)

- measure orbital velocity of stars (using Doppler shift)

Vera Rubin: The Dark Side of Galaxies (1970s)

- measure orbital velocity of stars (using Doppler shift)

- ‘flat’ rotation curves:
 - galaxies must contain 10 times more non-visible matter!

Through a Universe Darkly

- BIG Q: What is the dark matter?

???

- more than 70 years after it was first posulated by Zwicky, this remains one of the great unsolved problems in science!
- But, by trial and error, we ve gained important clues

Yakov B. Zeldovich: Godfather of Soviet Physics

- 1914 - 1987
- 'father' of Soviet Bomb (Atomic and Hydrogen)
- great astrophysicist:
 - supermassive black holes
 - no-hair theorem
- 'Zeldovich pancakes':
 - top-down theory of galaxy formation
 - neutrinos make up dark matter

The Neutrino Universe

- neutrinos: - very elusive (weakly interacting)
- they are *known* to exist!

Reines and Cowan beside one of their neutrino detectors. The experiment was jokingly called "Project Poltergeist" since the neutrino was considered to be as elusive as a ghost.

Reines and Cowan assumed that (anti)neutrinos $\bar{\nu}$ could be part of the radiation from nuclear reactors.

They let the radiation pass through a mixture of water and cadmium (Cd) chloride.

A neutrino that interacts with a hydrogen nucleus (p) can start the reaction which is shown in the figure.

The proof that a neutrino had been caught was obtained by registering the characteristic pattern of photons (γ).

γ gamma

The Neutrino Universe

- neutrinos: - produced in Big Bang fireball
- travel (almost) with speed of light

1 cm³

~115 neutrinos from Big Bang

- *If* neutrinos had (tiny) mass:
 - total mass of neutrinos in universe huge:

$$\text{Total Mass} = N \times \text{mass_nu}$$

The Neutrino Universe

- *If* $\text{mass}_{\nu} \sim 1/10,000 \times \text{mass}_{\text{electron}}$:

- there would be sufficient mass to `close' the universe
- Thus: Neutrinos could be very important on cosmic scales!

The Neutrino Universe

- Briefly after Big Bang: Matter and energy is distributed very smoothly

- but not quite: there are tiny irregularities ('lumps')
- smallest lumps grow fastest under gravity
- What is their fate?

The Neutrino Universe

- Q: How much mass is needed to confine (corral in) neutrinos?
- Early on (first 10,000 years), neutrinos move (almost) with speed of light (thus: 'Hot Dark Matter')

✱ neutrino

● Normal particles

Small mass

à Small structures
are 'erased' by
neutrino free-streaming!

Large mass

~ 10^{15} solar masses
à mass of a cluster
of galaxies (e.g., Coma)

The Neutrino Universe

- Zeldovich pancakes: Galaxies form from the 'top down'

- Prediction: clusters form *before* galaxies do!

The Neutrino Universe

- May 1980: 'Neutrino Spring'
 - Soviet physicist V.A. Lubimov claims that neutrinos have large enough mass to close the universe ($\sim 1/10,000$ mass_{electron})

- Was dark matter riddle solved?
- Alas, no:
 - Lubimov experiment proved wrong
 - astronomers contradict top-down scenario of galaxy formation

The Neutrino Universe Undone

- early 1980s:
 - dwarf galaxies have dark matter halos, too!
 - clusters of galaxies form late in history of universe, after the galaxies themselves!

- The neutrino universe doesn't work!
- Again: What *is* the dark matter???

The Cold Dark Matter Model

- 1984-86: postulate some mysterious particle that is massive, but only interacts weakly with ordinary matter other than through gravity (Blumenthal, Faber, Primack & Rees; Peebles)
- WIMPs = Weakly Interacting Massive Particles

- Normal particle
- WIMP

- small lumps survive!
- sub-galactic (million solar mass objects form first)!

The Cold Dark Matter Model

- Galaxies form from the 'bottom up' (hierarchical)

- Prediction: clusters form *after* galaxies do!

The Cold Dark Matter Model

- Structure forms from the 'bottom up' (hierarchical)

- Computer simulations: galaxies form before clusters!

The Cold Dark Matter Model

- But what is the WIMP really???
- Has not yet been directly detected!
- But there is a promising candidate:
 - the lightest supersymmetric particle (photino)

The Cold Dark Matter Model

- for every normal particle, there is a supersymmetric ('shadow') partner
- the lightest one (the photino) cannot decay, and would thus have survived from the very early universe!

The Dark Side of the Universe

- 1930s: Missing mass problem realized (Zwicky)
 - galaxies in Coma cluster move too fast
 - there must be 10 times as much mass as can be seen
 - Zwicky's prediction largely ignored
- 1970s: Dark halos of galaxies inferred (Rubin & Ford)
 - stars in galaxies continue to rotate quickly, even beyond the extent of luminous galaxy
 - again: 10 times as much mass needed
 - this time, the evidence was overwhelming, and dark matter was universally accepted
- Hot vs Cold Dark Matter
 - Hot Dark Matter = neutrinos: top-down scenario
 - Cold Dark Matter = WIMPs: bottom-up scenario
